ABSTRACT
The Jutpani Lake is principal fresh water body located in Jutpani village of Dharni tahsil in Amravati district of Maharashtra state. Dharni is a tahsil place and it is 148 km north west side of Amravati and 80 km east side from Burhanpur Madhyapradesh. It is situated at about 500 m above the mean sea level. The Ostracods were studied from Oct 2016 to Sept 2017 during this period total 2 species of Ostracods were found in sample three sites A, B and C of Jutpani Lake.
Keywords: Jutpani lake, Ostracods diversity.

INTRODUCTION
Ostracods commonaly known as seed shrimps and also Ostracods class of a Crustacea and found in a wide variety of aquatic habitats. It is bivalve and appear like small seeds. The body of Ostracod is laterally compressed and protected by a bivalve like such as chitinous or calcareous valve or "shell". Ostracod occurs in both water standing as well as running water. The Ostracods this organisms very good food for the fishes and aquatic organisms (Tonapi, 1980).

Jutpani lake is 8 km south east side from Dharni Tahsil at about 500 m above mean sea level and is at 77°11’50”E longitude and 21°26’45” N latitude. Jutpani Lake receives the water from the surrounding catchment areas during the monsoon period. The area of Jutpani Lake is spread over 400 acres. The depth of water is 37 feet during the monsoon and 14 feet during the summer season. The water of this lake is primary used for washing, bathing, fishing activities, agriculture and other domestic purpose but now it is at a transitional state with respect to degradation.

MATERIAL AND METHOD
Sample for planktonic study were collected monthly from three sites of lake. The samples were collected in the morning hours between 8.30 a.m. to 10.30 a.m. 50 Lt. of water sample was filtrated through the plankton net made of bolting silk number 25 with mesh size 64 lime. The collected samples were allowed to settle down by adding Lugol’s Iodine. Normally sedimentation requires 24 hrs. after which supernatant was removed and concentrate was made up to 50 ml. depending the number of plankton and preserved in 5% formalin for further studies.

For the quantitative study the concentrated sample was shaken and immediately one drop of sample was taken on a clear micro side with the help of standard dropper the whole drop was then carefully covered with the cover glass and observed. Plankton identification up to genera and whenever possible upto species level was classified according to keys given by Prescott (1954), Edmonsonic (1959), Sehgal (1983), Adoni (1985), and APHA (1985) and standard analysis was undertaken as per Zar (2005).

Quantitative study of plankton was done by Sedgwick – Rafter Cell method

Sedgwick – Rafter Cell Method
The Sedgwick – Rafter Cell is a special kind of slide similar to the Haemocytometer. The cell has a 50 mm x 20 mm x 10 mm rectangular cavity that holds 1 ml. sample. The cell is moved in horizontal direction on the stage of an inverted microscope and plankton species encountered in the field are enumerated. A
number of replicate samples are enumerated to calculate plankton/lit.

\[
\text{Plankton (units/lit)} = \frac{n \times c}{v}
\]

Where,
- \( n \) = number of plankton in 1ml
- \( c \) = Volume of concentrate
- \( v \) = Volume of sample in lit.

**RESULT AND DISCUSSION:**

In the present investigation, 2 species were reported at all the three sampling sites A, B and C of the lake under study during Oct 2016 – Sept 2017.

In site A, during 2016-17, 2 species were recorded among which *Stenocypris sp* (79 no./lit) and *Cypris sp.* (33 no./lit).

In site B, during 2016-17, 2 species were recorded *Stenocypris sp.* (76 no./lit) and *Cypris sp.* (66 no./lit).

In site C, during 2016-17, 2 species were recorded. *Stenocypris sp* (70 no./lit) and *Cypris sp.* (36 no./lit).

Among the different species in site A, *Stenocypris sp.* was dominant by Ostracods, *Cypris sp.* In site B, *Stenocypris sp.* was dominant by Ostracods, *Cypris sp.* In site C, *Stenocypris sp.* was dominant by Ostracods, *Cypris sp.*

In the present investigation the Ostracods density is a maximum during the winter and minimum during the monsoon season. Patil, (2008) recorded the maximum population of Ostracods during the summer season and minimum during the monsoon season. Pejawar and Gurao, (2008) observed them only during monsoon and stated that these are pollution sensitive species. Nirmal Kumar, et. al., (2011) founded the maximum population of Ostracods during the summer season and minimum during the monsoon season of a Varasda wetland system Gadekar, (2014) observed maximum Ostracods population were reported in summer, in March month while minimum in monsoon season, i.e. in July month in Pangdi lake of Gondia of District Gondia, Maharashtra. Shashikant Sire, (2014) reported maximum Ostracoda population were observed in summer months and minimum in rainy season in Sunkadin Naik lake of Nagpur city (M.S.).

**CONCLUSION:**

In the present investigation, the maximum Ostracods during the winter season is probably due to availability of suitable food and favorable temperature and minimum density in monsoon season which could be due to dilution of water resulting in fewer nutrients and due to reduction of transparency and dissolved oxygen.
