ABSTRACT
This study compares the treatment of photocatalytic advanced oxidation processes (AOPs) of an aqueous solution containing O-Hydroxy benzoic acid and TiO2 with ZnO photo catalytic processes. The various advanced oxidation processes (AOPs) such as the UV/H2O2, UV/H2O2/TiO2 and UV/H2O2/ZnO were investigated for the degradation of substrate in lab-scale experiments. The experiments were carried out in a batch photo reactor using 8W low pressure mercury vapour lamp. Substrate concentration was determined by UV-Visible Spectrophotometer. The semi-log plot of substrate concentration versus time suggests first order kinetics. The effects of parameters viz. pH, photo catalyst doses and hydrogen peroxide were also examined.

Keywords: Advanced Oxidation Processes, O-hydroxy benzoic acid, Photo reactor, Degradation, Photo catalytic, First order kinetics

1. Introduction
New developments in the variety of fields have also led to the presence of new compounds in the effluent streams of processing plants, which are not readily degraded by the conventional effluent treatment methods [1-3]. Oxidation of organic pollutants present in water is an attractive method of treatment because, if carried to completion, it results in the conversion of carbon dioxide and water. Unfortunately, the direct oxidation of organic compounds by molecular oxygen at ambient conditions is, in most cases, too slow to be of kinetics and mechanism of the degradation processes any potential use. On the other hand, Advanced Oxidation Processes (AOPs) offers the most effective way of oxidizing organic contaminants to less harmful compounds [4-6]. Typically AOPs are ambient temperature and pressure process that involve in situ generation of highly reactive species such as hydroxyl radical (•OH). The •OH radicals are powerful oxidizing reagents with an oxidation potential of 2.80 V and exhibits faster rates of oxidation reactions as compared to that using conventional oxidants like hydrogen peroxide or KMnO4[4]. Among AOPs, photocatalytic oxidation (PCO) has proved to be of real interest as efficient tool for degrading aquatic organic contaminants. PCO involves the acceleration of photoreaction in presence of semiconductor photocatalyst. One of the major applications of PCO is heterogeneous photocatalysis to effect total mineralization of liquid phase organic contaminants. The term "photocatalytic degradation" usually refers to complete photocatalytic oxidation or photo mineralization, essentially to CO2 H2O, NO3 , PO4 and halide ions [5,6]. Metallic oxides and sulfides are among the most used semiconductor materials available for photocatalytic purposes. Nowadays, titanium dioxide (TiO2) is the most frequently used semiconductors for heterogeneous photocatalytic processes anytime it has demonstrated to be the most active[7,8]. Table 1 depicts some of the semiconductor materials used in photocatalytic reactions along with their band gap energy required for catalyst activation and the maximal wavelength required for activation. Degradation of organic pollutants by heterogeneous photocatalytic is among the most successful applications.

Dhanshvar et al reported [10] that ZnO is a better alternative for the degradation of dyes as its photodegradation mechanism is similar to that of TiO2. Lizama et al. [11] reported higher photocatalytic efficiency of ZnO in the colour removal of Reactive Blue 19. The biggest advantage of ZnO is that it can absorb over a larger fraction of UV spectrum[12]. Keeping this in view we focussed our work to compare the photocatalytic efficiency of TiO2 and ZnO. This may lead to cost effective treatment technology for most of the organic pollutants. Salicylic acid is chosen as a modern pollutant for the present study. Salicylic acid is very toxic and it is widely present in industrial effluents[13]. It can stimulate skin and mucous membrane and react with proteins. In addition, it can bring about tinnitus, qualm, naupathia and electrolytical turbulence. Hence this compound is selected for the present study.

2. Experimental

2.1 Chemicals
Analytical grade O-Hydroxybenzoic acid was purchased from Merck, India; and was used as received without any further purification and stock solution of 0.01M of O-Hydroxybenzoic acid was prepared. Initial concentration of O-Hydroxybenzoic acid used during the experimental runs was 0.15mM. Stock solution of H2O2 was prepared by diluting 30% w/v of hydrogen peroxide (Qualigens) with distilled water. All stock solutions were stored in amber coloured light resistant Pyrex glass bottles. TiO2 (AR) (surface area 50m2/g) and ZnO were obtained from s-d fine chemicals, India & were used as received. Sodium hydroxide (1N) and sulphuric acid (1N) were used for pH adjustments.

2.2. Experimental procedure
Batch experiments were conducted at room conditions to determine the effect of pH, H2O2 concentration, TiO2 doses & ZnO doses during degradation of O-Hydroxybenzoic acid. All experiments were conducted in a photo reactor (Fig.1) equipped with low pressure mercury lamp (8W, UV-C manufactured by Phillips, Holland) placed in its centre. During the reaction, the solution was stirred by magnetic pellet to ensure its homogeneity. Synthetic wastewater containing 0.15 mM solution of O-Hydroxybenzoic acid in double distilled water was used in this study. 750 ml of this synthetic wastewater was taken in the photo reactor and irradiated with UV lamp of 8W. Various experiments were carried out using UV light with oxidant at various stoichiometric ratios of oxidant/pollutant. The suspended TiO2 solution was mixed very well using stirrer for 30
minutes so that adsorption equilibrium was reached. The time at which the ultraviolet lamp was turned on was considered time zero or the beginning of the experiment. Samples were taken at regular time interval from the reaction vessel and pipette out into test tubes. Then a centrifugation process was applied to separate TiO2/ZnO catalyst particles after photo catalysis. The Samples were immediately analyzed to avoid further reaction. The overall degradation reaction was carried out for 240 min.

2.3. Analysis
The initial pH of the solution was measured using Elico pH meter LI-120 equipped with a combined calomel-glass electrode. The UV-visible spectrophotometric method was used for measurement of O-Hydroxybenzoic acid and H2O2 concentration in aqueous solution. A UV-visible spectrophotometer (Spectrascan UV 2600, Chemito, India) was used for this purpose. A calibration plot between absorbance and concentration of O-Hydroxybenzoic acid was plotted experimentally, which gave a high linear regression coefficient of 0.996 at 229.5 nm (Fig.2).

3. Results & Discussion
3.1. Effect of pH
pH is one of the most important parameters to be studied. The rate of degradation of O-Hydroxybenzoic acid was observed by carrying out the experiments at different pH conditions namely 2, 3, 4, 5, 6, 7 and 9. In case of H2O2/UV, the maximum degradation O-Hydroxybenzoic acid was achieved at pH 7 and shows decreasing trend of degradation at higher and lower pH

![Fig. 1 - Photoreactor](image)

![Fig. 2- Calibration Curve of O-Hydroxy benzoic acid](image)

![Fig. 3- Effect of pH on degradation efficiency for O-Hydroxy benzoic acid](image)
3.2 Effect of dose of H$_2$O$_2$/COD ratio on degradation of O-Hydroxy benzoic acid
By carrying out a series of experiments of O-Hydroxybenzoic acid (with different ratio of H$_2$O$_2$/COD namely 2, 3, 4, 5, 6 & 7); the optimum H$_2$O$_2$ stoichiometric ratio was found to be H$_2$O$_2$ /COD=5 (Fig. 4). Further increase in H$_2$O$_2$ concentration lowered the degradation rate. This is because of the excess H$_2$O$_2$reacts with the hydroxyl radicals earlier formed and hence acts as an inhibiting agent of degradation by consuming the hydroxyl radicals responsible for degrading the pollutants [14].

![Fig.4- Effect of initial H$_2$O$_2$/COD on degradation efficiency for O-Hydroxy benzoic acid (conditions: [O-HBA] = 0.15 mM, pH = 7)](image)

3.3 Effect of catalyst doses
The experiments were conducted to study the effect of varying catalyst doses from 10mg/lit to 90mg/lit for the degradation efficiency of O-Hydroxybenzoic acid. Application of both oxidant and photocatalyst enhances the degradation mechanism and hence gives much higher removal. Maximum degradation of 93.14% was observed with 70 mg of catalyst TiO$_2$ & 89.62% with70 mg ZnO photocatalyst. Bar diagram (Fig. 5) shows comparison of efficiency of the oxidative degradation photo catalytic processes using photocatalysts TiO$_2$ & ZnO. It was observed that the increase in amount of catalyst loading increases the rate of degradation up to a certain catalyst amount. The increase in degradation rate may be explained by the fragmentation of catalyst which produces higher surface area. Thereafter with further increase in catalyst loading the degradation rate starts declining. This nature is due to the screening effect i.e., above a certain amount of catalyst loading, the turbidity of the solution increases and ultraviolet rays start getting scattered, hence reducing the optical path [15]. Aggregation of catalyst particles, which reduced the interfacial area between the reaction solution & the photo catalyst, may be other reasons for the degradation rate.

![Fig. 5- Bar diagram showing rate of degradation of O-Hydroxy benzoic acid with photo catalyst TiO$_2$ and ZnO](image)

4. Comparison of various AOPs studied and the kinetic studies
A comparison study was carried out for degradation of O-Hydroxy benzoic acid at optimum conditions for different AOPs studied viz. UV/H$_2$O$_2$, UV/TiO$_2$/H$_2$O$_2$ and UV/H$_2$O$_2$/ZnO. It was found that the rate of degradation is highest when the combination-UV/TiO$_2$/H$_2$O$_2$ was used.

5. Degradation Rate Kinetics
The semi logarithmic graph of the concentration of O-Hydroxybenzoic acid with time yield a straight line indicating the reaction is of pseudo
first order (eq. 1)

\[ \ln \left( \frac{C_t}{C_0} \right) = -K \cdot t \]  \hspace{1cm} (1)

where \( C_0 \) and \( C_t \) are the concentration of pollutant at irradiation times 0 and \( t \), \( K \) is a first-order rate constant (min\(^{-1}\)) and \( t \) is the irradiation time (min).

\[-\frac{d}{dt}[C(X)] = k \cdot C(X)(B) \]  \hspace{1cm} (2)

Where \( C(X) \) is the concentration of substrate

For O-Hydroxy benzoic acid, first order reaction was found to have maximum value of \( R^2 \) as compared to the second order. Hence kinetic constant based on O-Hydroxybenzoic acid degradation found to follow first order kinetics. Table 2 gives the first order rate constant for UV/\( \text{H}_2\text{O}_2/\text{TiO}_2 \) system.

On the basis of the results obtained, the following reaction scheme is proposed as the most probable reaction mechanism for the photodegradation of O-hydroxybenzoic acid.
6. Conclusion
This study showed the potentialities of photocatalytic degradation in water purification. Out of different processes employed, a significant enhancement of the photocatalytic activity was observed in the system using combination of oxidant and photocatalyst irradiated under UV light. Concentration of both oxidant and photocatalyst greatly influences the degradation rate. Also the process was observed to be strongly pH dependent. The degradation follows pseudo first-order kinetics. Photo degradation can be a recommended approach for the treatment of wastewater containing O-Hydroxy benzoic acid. Keeping in view all the factors, it can be easily said that UV/H2O2/TiO2 system is an efficient one amongst all other processes studied. The best reaction dose of TiO2 was found to be 70 mg/lit. Hence TiO2 was found to be more efficient than the photocatalyst ZnO in the degradation of the selected pollutant substrate.
